

ASSET PRICING - EMPIRICAL APPLICATION 1

FACTORIAL MODEL AND RISK PREMIUM DECOMPOSITION - APT

Luis Miguel Fonseca
Stéphane Eloundou Mvondo
Natalia Cárdenas Frías

November 27, 2023

Introduction

Focusing on recent data from the French equity market, we want to better comprehend how the market prices systemic, non-diversifiable risk embedded in the risk premium of stocks, i.e. any expected compensation beyond the risk-free return. We base our analysis on a linear decomposition of said premium on different *factors* of risk in the spirit of the Arbitrage Pricing Theory (APT) pioneered by Ross [1976]. Unlike the CAPM model which considers a unique risk premium in the market, the Ross model gives a more detailed description of the pricing of aggregate risk by decomposing the contributions of different sources of risk. Here, a risky portfolio of j stocks¹ is compensated with k risk premia associated with the k *common factors* that the portfolio is exposed to.

1 Data and Framework

1.1 French stock market data

We decided to build a case study of the French market because it is a liquid and matured market, central in Europe. In the case of this analysis, we had trouble getting the data needed to perform it for other countries² and the fact that France has more publicly available data helped us choose it as our market of study.

We built a portfolio with 30 French stocks that we got from Yahoo Finance. For simplicity, the synthetic portfolio is composed of one stock of each company and its composition does not change during the period studied. Table 1 shows the companies that we used to create this portfolio, they are all publicly traded companies in France since the early 2000's in Euronext Paris. Importantly, we tried to have a certain diversity in the sectors

¹Let $j \in \{1, \dots, J\}$ with J sufficiently large so that all idiosyncratic risk can be fully diversified. We better explain the difference between idiosyncratic and aggregate in the context of the Ross model in Section 1.1

²Initially we thought about using data from the German market but we couldn't for instance find data for their inflation-linked bond yield that we use as an endogenous factor in Section 2.1.2

represented to be able to capture some diversification to risk even if the portfolio is too small and we do not reweight it. However, because we try to implement a version of the [Fama and French \[1992\]](#) factor analysis, we restrain ourselves from choosing financial companies as the authors do due to their high leverage. Other than these two conditions, the choice of the companies was mainly restricted to data availability on public 'long' series on firm-level data, notably on market capitalization and book-to-market ratio to be able to incorporate the [Fama and French \[1992\]](#) factors to our analysis.

describe frequency of data

Because we are interested in the underlying determinants of the risk premia, and due to data availability issues, we decided to have a broad analysis at the

Company Name	Ticker	Industry
Accor	AC.PA	Hospitality
Air Liquide	AI.PA	Industrial Gases
Air France-KLM	AF.PA	Airlines
Airbus	AIR.PA	Aerospace
Biomerieux	BIM.PA	Biotechnology
BIC	BB.PA	Consumer Goods
Bouygues	EN.PA	Construction
Capgemini	CAP.PA	Information Technology
Carrefour	CA.PA	Retail
Casino	CO.PA	Retail
Dassault Aviation	AM.PA	Aerospace
Danone	BN.PA	Food and Beverage
Hermes International	RMS.PA	Fashion and Luxury
JCDecaux	DEC.PA	Advertising
Kering	KER.PA	Fashion and Luxury
L'Oreal	OR.PA	Cosmetics
LVMH	MC.PA	Fashion and Luxury
Michelin	ML.PA	Automotive
Nexans	NEX.PA	Electrical Equipment
Orange	ORA.PA	Telecommunications
Renault	RNO.PA	Automotive
Saint-Gobain	SGO.PA	Manufacturing
Sanofi	SAN.PA	Pharmaceuticals
Sodexo	SW.PA	Food Services
TF1	TFL.PA	Broadcasting
Thales	HO.PA	Aerospace and Defense
TotalEnergies	TTE.PA	Energy
Ubisoft	UBI.PA	Video Games
Vinci	DG.PA	Construction
Vivendi	VIV.PA	Entertainment

Table 1: Synthetic portfolio: Companies, Tickers, and Industries

1.1.1 Data description and sources

The other series that we use are the following and its sources, how they are used in the context of the analysis is described in subsequent sections.

- As a proxy for the free rate of the market we consider two measures:
 - The yield of short-term OAT, i.e. French treasuries taken from [Banque de France's website](#). As for most developed, stable countries, short-term sovereign bonds are taken as the risk-free asset as Governments are supposed to be more solvent than other agents in the economy, after all, they decide their income and could seize resources via taxes to meet their obligations.
 - The spot yield curve spot rate, for 3-month maturity of all government bonds rated triple A in the Euro Area, retrieved from the [ECB webpage](#). On top of the fact that this is a measure for short-term sovereign bonds, we consider this to be a relevant proxy for the French market due to the strong integration within the European capital market. If an investor decides that the French market becomes risky, she can easily move her investments to another European capital market that looks safer.
- To get the market rate, we use the return of the main index of the country, the CAC40 also taken from Yahoo Finance as for the components of our synthetic portfolio. In hindsight, we are not sure of the pertinence of comparing our portfolio to this index. While the composition of our portfolio is not the same as the CAC40³, due to the data availability issues we've been mentioning, we see that our choices are heavily biased towards 'big name' companies that are those belonging to the index.
- We got the series of the exchange rate between the Euro and the US dollar from Yahoo Finance.
- The GDP series is taken from the [ECB webpage](#). It is available at a quarterly frequency and is available at market prices.
- The harmonized headline inflation rate is taken from the [INSEE webpage](#).
- For the market inflation expectation in a 10-year horizon, we use the break-even inflation rate published by [Agence France Trésor](#) online. Sadly, data is only available from 2013.
- For the implementation of the two additional [Fama and French \[1992\]](#) factors, we took different routes
 - We found the estimation of the factors published by K. French in his [online Data Library](#) that are constantly updated. Their estimations start in the 1990s and are made for different markets using the comprehensive CRSP dataset that is not freely available. He has an estimation for the European market that we downloaded to use but it is not clear which stocks are used to replicate their portfolio.
 - To try to build these estimations ourselves for our portfolio meaning that a minima we need data on the market capitalization of each company during the time frame studied and its *book*. This information is hardly available without having access to platforms like Bloomberg or CRSP. The best information that we could find comes from [this](#) website that publishes the market capitalization and the price-to-book (the inverse of the book-to-market ratio) annual series for several stocks. The data is however cannot be directly downloaded from the site so we scrap it to get the series (see Code Appendix A). Our biggest fear with this source is that it is not clear at all where the information

³Not all the stocks we chose are necessarily part of the CAC40 at every period studied, and the CAC40 is a weighted index that evolves over time.

comes from even if they mention several quality [data providers](#) as their partners. Since it is the only source that resembles what is needed for this part we used it but we are not confident on it.

1.2 Factorial model and multibeta relationship

For the sake of completeness, this section summarizes the lecture on the [Ross \[1976\]](#) model and the multibeta relationship as they are the theoretical foundation of the empirical application.

Let the return R_j of the j -th component of her portfolio can be described by the following expression $\forall j \in \{1, \dots, N\}$:

$$R_j = \mathbb{E}[R_j] + \underbrace{\sum_{k=1}^K \beta_{j,k} f_k}_{\text{Systemic risk}} + \overbrace{u_j}^{\text{Idiosyncratic risk}} \quad (1)$$

Where $\mathbb{E}[R_j]$ is the expected return of asset j . The sources of risk are two-fold. The investor faces centered idiosyncratic risks u_j , $\mathbb{E}[u_j] = 0$ that are assumed to be completely diversifiable with a portfolio "large enough" (N big) because they are independent of each other $u_j \perp u_{j'} \forall j \neq j'$, and uncorrelated with aggregate risk $\text{corr}(u_j, f_k) = 0, \forall j, k$ which is a required assumption to perform the estimations that will follow. She also faces k different sources of aggregate risk, modeled by the linear combination of f_k centered *shocks* that influence all R_j with a sensitivity β_{jk} . By definition, these risks cannot be diversified because they affect the returns of all asset and thus has to be compensated which is the focal point of our study.

2 Empirical strategy and implementation

2.1 Identify the risk factors

2.1.1 Exogeneous factors

2.1.2 Endogeneous factors

2.1.3 French-Fama factors

2.2 Estimate the β_k coefficients from the factorial model

2.3 Estimate the λ_k parameters from the multibeta relationship

2.4 Test the validity of the multibeta relationship

Conclusion

3 Data and Framework

3.1 German Stock Market

We decided to consider the German stock market for this analysis because it is a major liquid stock market in Europe. It is also the biggest economy in the Europe, with mayor

3.2 Estimation of the Factors

We need to choose what factors we are going to consider to generate risk premia that affect the return for the investor. In this section we examine the role of different types of factors (i) exogenous, (ii) endogeneous and we examine more closely the three-factor model proposed by [Fama and French \[1993\]](#) in (iii).

3.3 Exogeneous Factors

These are risk factors that are supposed to be orthogonal to the portfolio itself. In particular, it is interesting to consider the role of

3.4 Endogeneous Factors

3.5 French-Fama Factors

[Fama and French \[1993\]](#) can be seen as an extension of the CAPM model. The authors show that the variation of the returns of an asset can be explained not only by the exposure to market risk as in the CAPM represented by the difference of the market return and the risk-free rate $[R_M - R_f]$, but also by a size and value premium in the following model.

$$R_j = \alpha_j + R_f + \beta_{m,j}[R_M - R_f] + \beta_S SMB + \beta_V HML + \varepsilon_j \quad (2)$$

The size premium refers to the observation that stocks with small market capitalizations tend to outperform stocks with larger ones and it is captured by the factor SMB, *small minus big*. It is computed as the difference in average returns of the 30% stocks with the smallest market capitalization and the average returns of the 30% stocks associated with the firms with the largest market capitalization. The value premium refers to the outperformance of "value stocks" i.e. those that have high book-to-market (B/M) and it is represented by the difference in an average return of the 50% of stocks with the highest B/M ratio (value stocks) and the 50% with lowest B/M ratio (growth stocks).

4 Estimation of the exposure

5 Estimation of the market price of risk(s)

Consider a series of returns for different stock prices of at least 30 over a given period of time and frequency. The goal is to estimate risk premium by choosing a relevant so-called risk-free asset obtained as the return of treasury bond with relevant maturity

Develop econometric analysis which provides the multi-beta relationship 1. Identify the series for the risk factors (endo and exo) and justify choices + including 2 factors proposed by French and Fama 2. Estimate beta coefficients for different stocks with relevant linear regression 3. Estimate market price of different sources of risk retained in analysis with appropriate linear regression

Comment the results from a financial point of view: are the estimated exposures of the different stocks to the different factors in line with expectations
